From Designing a Digital Future

Progress in algorithms beats Moore's law

Everyone knows Moore's Law — a prediction made in 1965 by Intel co-founder Gordon Moore that the density of transistors in integrated circuits would continue to double every 1 to 2 years.

Even more remarkable — and even less widely understood — is that in many areas, performance gains due to improvements in algorithms have vastly exceeded even the dramatic performance gains due to increased processor speed.

In the field of numerical algorithms, the improvement can be quantified. Here is just one example. A benchmark production planning model solved using linear programming would have taken 82 years to solve in 1988, using the computers and the linear programming algorithms of the day. Fifteen years later — in 2003 — this same model could be solved in roughly 1 minute, an improvement by a factor of roughly 43 million. Of this, a factor of roughly 1,000 was due to increased processor speed, whereas a factor of roughly 43,000 was due to improvements in algorithms!

CS 355 (USNA) Unit 1 Spring 2012 1 / 30

Why study algorithms?

- It's all about efficiency!
- We will make heavy use of abstractions.
- Solving difficult problems, solving them fast, and figuring out when problems simply cannot be solved fast.

 $\mathsf{CS}\ \mathsf{355}\ \ \mathsf{(USNA)} \qquad \qquad \mathsf{Unit}\ \mathsf{1} \qquad \qquad \mathsf{Spring}\ \mathsf{2012} \qquad \mathsf{2}\ \mathsf{/}\ \mathsf{30}$

Definition of a Problem

A *problem* is a collection of input-output pairs that specifies the desired behavior of an algorithm.

Example (Sorting Problem)

- [20, 3, 14, 7], [3, 7, 14, 20]
- [13, 18], [13, 18]
- [5, 4, 3, 2, 1], [1, 2, 3, 4, 5]

•

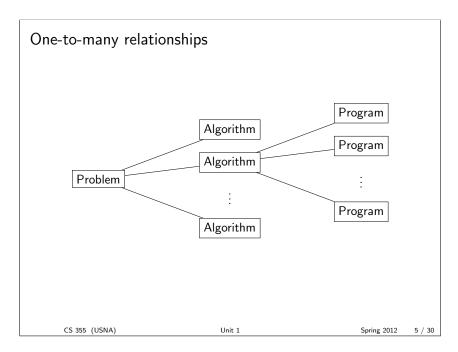

CS 355 (USNA) Unit 1 Spring 2012 3 / 30

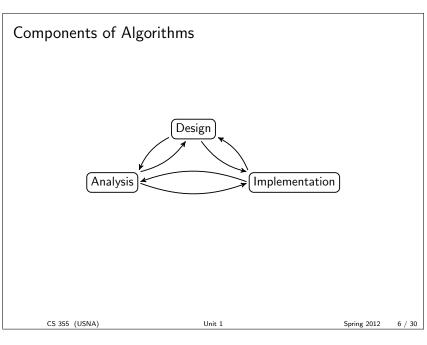

Algorithm Definition

An $\emph{algorithm}$ is a specific way to actually compute the function defined by some problem.

- Must produce correct output for every valid input
- Must terminate in a finite number of steps
- Behavior is undefined on invalid input
- Independent of any programming language or architecture

CS 355 (USNA) Unit 1 Spring 2012 4 / 30

Foci of the course

- Design: How to come up with efficient algorithms for all sorts of problems
- **Analysis**: What it means for an algorithm to be "efficient", and how to compare two different algorithms for the same problem.
- **Implementation**: Faithfully translating a given algorithm to an actual, usable, fast program.

Unit 1

Spring 2012 7 / 30

Sorted Array Search Problem

Problem: Sorted array search

Input:

- A, sorted array of integers
- x, number to search for

Output:

• An index k such that A[k] = x, or NOT_FOUND

CS 355 (USNA)

Unit 1

Spring 2012 8 / 30

Algorithm: linearSearch

Input: (A, x), an instance of the Sorted Array Search problem

```
1 i = 0
```

2 while i < length(A) and A[i] <
$$x$$
 do

$$i = i + 1$$

- 4 if i < length(A) and A[i] = x then return i
- 5 else return NOT_FOUND

CS 355 (USNA) Unit 1 Spring 2012 9 / 3

```
Algorithm: binarySearch
Input: (A, x), an instance of the Sorted Array Search problem
  _{2} right = length(A)-1
     while left < right do
  3
          middle = floor((left+right)/2)
          if x <= A[middle] then</pre>
              right = middle
  6
          else if x > A[middle] then
  7
              left = middle+1
  8
          end if
  9
  10 end while
  if A[left] = x then return left
    else return NOT_FOUND
    CS 355 (USNA)
                             Unit 1
                                                 Spring 2012 10 / 30
```

Algorithm: gallopSearch

Input: (A, x), an instance of the Sorted Array Search problem

```
1  i = 1
2  while i < length(A) and A[i] <= x do
3          i = i * 2
4  left = floor(i/2)
5  right = min(i, length(A)) - 1
6  return binarySearch(A[left..right])</pre>
```

CS 355 (USNA)

Unit 1

Spring 2012 11 / 30

Loop Invariants

- 1. **Initialization**: The invariant is true at the beginning of the first time through the loop.
- 2. **Maintenance**: If the invariant is true at the beginning of one iteration, it's also true at the beginning of the next iteration.
- 3. **Termination**: After the loop exits, the invariant PLUS the loop termination condition tells us something useful.

CS 355 (USNA) Unit 1 Spring 2012 12 / 30

Choices in Implementation

- What programming language to use
- What precise language constructs to use (For example, should the list be an array or a linked list? Should we actually call the "length" function on the list every time, or save it in a variable?)
- What compiler to use, and what compiler options to compile with.
- What machine/architecture to run on

CS 355 (USNA)

Unit 1

Spring 2012 13 / 30

Timing Experiments

Input	X	Result	linear	binary	gallop
[6 7 8]	4	NOT	5	5	7
[27 50 62 78 180]	62	2	6	7	12
[3 6 23 27 990]	500	NOT	76	14	25
[7 11 14 17 99997]	19	4	8	31	15
[14 17 28 58 999992]	966	99	128	53	27
[0 2 2 3 9998]	9999	NOT	12108	35	59

• Which one is the fastest?

CS 355 (USNA)

Unit 1

Spring 2012 14 / 30

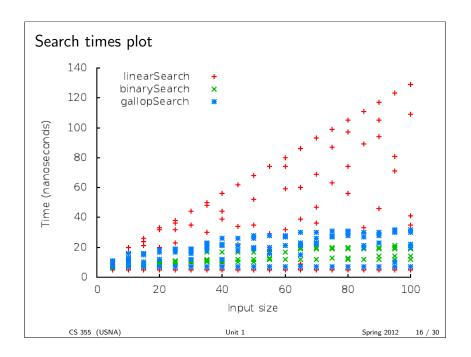

Measure of Difficulty

- Need a way to put timings in context should spend more time on harder inputs.
- Need to sort the data so we can make sense of it.

Solution: assign a difficulty measure to each input.

Most common measure: **input size**, *n*.

CS 355 (USNA) Unit 1 Spring 2012 15 / 30

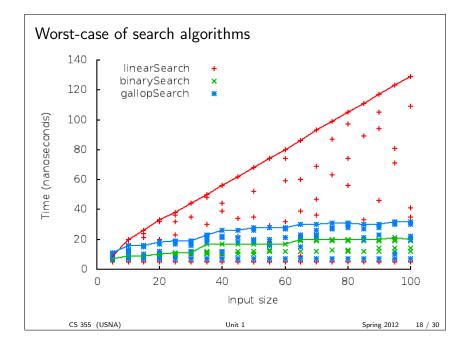

Making a single function for run-time

- Best-case: Choose the best (smallest) time for each size
- Worst-case: Choose the worst (largest) time for each size
- Average-case: Choose the average of all the timings for each size

Of these, the worst-case time is the usually the most significant.

CS 355 (USNA) Unit 1 Spring 2012 17 / 30

Shortcomings of experimental comparison

- It depends on the machine.
- It depends on the implementation.
- It depends on the examples chosen for each size.
- It depends on the sizes chosen.
- Can't describe how much better one algorithm is than another.
- Implementations are expensive (time, cost) to create.

Formal analysis will overcome these shortcomings, but requires some more simplifications.

CS 355 (USNA) Unit 1 Spring 2012 19 / 30

Abstract Machine

To achieve *machine independence*, we usually count the number of operations in an *abstract machine model* such as a RAM.

That's too hardcore for us. Instead, we will count:

Definition (Primitive Operation)

A *primitive operation* is one that can be performed in a fixed number of steps on any modern architecture.

- Intentionally vague definition
- Examples: integer addition, memory lookup, comparison

CS 355 (USNA) Unit 1 Spring 2012 20 / 30

Primitive count analysis

CS 355 (USNA) Unit 1 Spring 2012 21 / 30

Asymptotic Notation

- Counting primitive operations exactly is too precise and doesn't help to compare algorithms
- Solution: Big-O, Big- Ω , Big- Θ

Definition (Big-O Notation)

Given two functions T(n) and f(n), that always return positive numbers, $T(n) \in O(f(n))$ if and only if there exist constants $c, n_0 > 0$ such that, for all $n \ge n_0$, $T(n) \le cf(n)$.

CS 355 (USNA)

Unit 1

Spring 2012 22 / 30

Big-O Simplification Rules 1

Constant multiple rule

If $T(n) \in O(f(n))$ and c > 0, then $T(n) \in O(c * g(n))$.

Domination rule

If $T(n) \in O(f(n) + g(n))$, and $f(n) \in O(g(n))$, then $T(n) \in O(g(n))$. (In this case, we usually say that g "dominates" f.

Transitivity rule

If $T(n) \in O(f(n))$ and $f(n) \in O(g(n))$, then $T(n) \in O(g(n))$.

CS 355 (USNA)

Unit 1

Spring 2012 23 / 30

Big-O Simplification Rules 2

Addition rule

If $T_1(n) \in O(f(n))$ and $T_2(n) \in O(g(n))$, then $T_1(n) + T_2(n) \in O(f(n) + g(n))$.

Multiplication rule

If $T_1(n) \in O(f(n))$ and $T_2(n) \in O(g(n))$, then $T_1(n) * T_2(n) \in O(f(n) * g(n))$.

Trivial rules

For any positive-valued function f:

- $1 \in O(f(n))$
- $f(n) \in O(f(n))$

CS 355 (USNA) Unit 1 Spring 2012 24 / 30

$\mathsf{Big}\text{-}\Omega$ and $\mathsf{Big}\text{-}\Theta$

Definition (Big- Ω)

 $T(n) \in \Omega(f(n))$ if and only if $f(n) \in O(T(n))$.

Definition (Big- Θ)

 $T_1(n) \in \Theta(T_2(n))$ if and only if both $T_1(n) \in O(T_2(n))$ and $T_2(n) \in O(T_1(n))$.

• Which of the previous rules apply for these?

CS 355 (USNA)

Unit 1

Spring 2012 25 / 30

Worst-case running times

- linearSearch is $\Theta(n)$ in the worst case
- binarySearch is $\Theta(\log n)$ in the worst case
- gallopSearch is $\Theta(\log n)$ in the worst case too!
- What does this all mean?

CS 355 (USNA)

Unit 1

Spring 2012 26 / 30

Don't mix up worst/best/average case with big-O/big- Ω /big- Θ .

CS 355 (USNA) Unit 1 Spring 2012 27 / 30

Different difficulty measure

- Observation: linearSearch and gallopSearch perform better when the search key x is very small.
- Alternate difficulty measure: m, the least index such that $A[m] \ge x$.
- \bullet Re-do the analysis in terms of m and n.

CS 355 (USNA)

Unit 1

Spring 2012 28 / 30

A different cost function

What if we counted comparisons instead of primitive operations?

- linearSearch:
- binarySearch:
- gallopSearch:

CS 355 (USNA)

Unit 1

Spring 2012 29 / 30

Conclusions

- Which search algorithm is the best?
- Design, Analysis, Implementation
- Problem, Algorithm, Program
- Best-case, worst-case, and average-case
- Φ Big-O, Big-Ω, Big-Θ

CS 355 (USNA) Unit 1 Spring 2012 30 / 30
