Why	Number Theory?	
Number Theory		
Number Theory is the stud	ly of integers and their r	esulting <i>structures</i> .
,	,	0
Why study it?		
 History: the first true 	algorithms were number	-theoretic.
② Analysis: We'll learn a	about new kinds of runni	ng times and analyses.
③ Cryptography! Moder	n cryptosystems rely hea	wily on this stuff.
④ Computers are always	dealing with integers an	yway!
SI 335 (USNA)	Unit 3	Spring 2015 1 / 30
The	size of an integer	
How big is an integer	.?	
The measure of difficulty	for array-based problem	is was always the size of
the array.	, , , , , , , , , , , , , , , , , , ,	2
		2
What should it be for an a	Igorithm that takes an ir	nteger n?
SI 335 (USNA)	Unit 3	Spring 2015 2 / 30
The	size of an integer	
Factorization		

Classic number theory question: What is the **prime factorization** of an integer n?

Recall:

- A prime number is divisible only by 1 and itself.
- ${\ensuremath{\, \circ \, }}$ Every integer >1 is either prime or composite.
- Every integer has a unique prime factorization.

It suffices to compute a *single* prime factor of n.

Th	e size of an integer	
leastPrimeFactor		
Input: Positive integer n		
Output: The smallest prin	me p that divides n	
def leastPrimeFacto	or(n):	
i = 2		
while 1 * 1 <= if n % i ==	n: = 0:	
return	i	
i = i + 1		
Teculi II		
Running time:		
Is this fast??		
SI 335 (USNA)	Unit 3	Spring 2015 4 / 30
Th	e size of an integer	
Polynomial Time		
Folynonnal Time		
The actual running time	in terms of the size $c \in \Theta(I)$	or n) of n is $\Theta(2^{s/2})$
The actual fullning time,	In terms of the size $3 \in O(n)$	$\log n$ of n , is $O(2^{n})$.
Definition		
An algorithm runs in pol	ynomial time if its worst-ca	se cost is $O(n^c)$ for
some constant c.		
Why do we care? The fol	llowing is sort of an algorith	mic "Moore's Law":
Cobham-Edmonds Thes	sis	
An algorithm for a comp	itational problem can be fea	sibly solved on a
computer only if it is poly	ynomial time.	
So our integer factorization	on algorithm is actually reall	ly slow!
SI 335 (USNA)	Unit 3	Spring 2015 5 / 30
Ν	Modular Arithmetic	
Modular Arithmetic		
Division with Remainde	r	
For any integers a and m	with $m > 0$ there exist int	egers a and r with
$0 \le r < m$ such that	with $m > 0$, there exist lift	
_	a = qm + r.	

We write a mod m = r. Modular arithmetic means doing all computations "mod m".

Modular Addition

This theorem is the key for efficient computation:

Theorem

For any integers a, b, m with m > 0,

 $(a+b) \mod m = (a \mod m) + (b \mod m) \mod m$

Subtraction can be defined in terms of addition:

• a-b is just a+(-b)

• -b is the number that adds to b to give 0 mod m

• For
$$0 < b < m, -b \mod m = m - b$$

The Euclidean Algorithm

Computing GCD's

```
The greatest common divisor (GCD) of two integers is the largest
number which divides them both evenly.
Euclid's algorithm (c. 300 B.C.!) finds it:
GCD (Euclidean algorithm)
Input: Integers a and b
Output: g, the gcd of a and b
def gcd(a, b):
     if b == 0:
          return a
     else:
          return gcd(b, a % b)
Correctness relies on two facts:
  • gcd(a, 0) = a
  • gcd(a, b) = gcd(b, a \mod b)
                                                          Spring 2015

The Eu	iciidean Algorithm					
Worst-case of Euclidean Algorithm						

Definition

The Fibonacci numbers are defined recursively by:

- $f_0 = 0$
- $f_1 = 1$
- $f_n = f_{n-2} + f_{n-1}$ for $n \ge 2$

The worst-case of Euclid's algorithm is computing $gcd(f_n, f_{n-1})$.

SI 335 (USNA)

Unit 3

Spring 2015 17 / 30

Extended Euclidean Algorithm

Computing gcd(a, m) tells us whether $a^{-1} \mod m$ exists. This algorithm computes it:

The Euclidean Algorithm

```
Input: Integers a and b
Output: Integers g, s, and t such that g = GCD(a,b) and as + bt = g.
def xgcd(a, b):
    if b == 0:
        return (a, 1, 0)
    else:
        q, r = divmod(a, b)
        (g, s0, t0) = xgcd(b, r)
        return (g, t0, s0 - t0*q)
```

Notice: $bt = g \mod a$. So if the gcd is 1, this finds the multiplicative inverse!

Cryptography

Basic setup:

(1) Alice has a message M that she wants to send to Bob.

Encryption

- ② She encrypts *M* into another message *E* which is gibberish to anyone except Bob, and sends *E* to Bob.
- 3 Bob decrypts E to get back the original message M from Alice.

Generally, M and E are just big numbers of a *fixed size*.

So the full message must be encoded into bits, then split into *blocks* which are encrypted separately.

А	В	С	D	E	F	G	Η	Ι	J	Κ	L	M
0	1	2	3	4	5	6	7	8	9	10	11	12
N	0	Р	Q	R	S	Т	U	V	W	X	Y	Z
N 13	0 14	Р 15	Q 16	R 17	S 18	T 19	U 20	V 21	W 22	X 23	Y 24	Z 25

Public Key Encryption

Traditionally, cryptography required Alice and Bob to have a **pre-shared key**, secret to only them.

Encryption

Along came the internet, and suddenly we want to communicate with people/businesses/sites we haven't met before.

The solution is **public-key cryptography**:

- Bob has two keys: a public key and a private key
- ² The public key is used for encryption and is published publicly
- 3 The private key is used for decryption and is a secret only Bob knows.

- 2 Choose e such that $2 \le e < (p-1)(q-1)$ and gcd((p-1)(q-1), e) = 1.
- 3 Compute $d = e^{-1} \mod \varphi(n)$ with the Extended GCD algorithm
